Harry Hapless is a friend struggling to finish his Lab; knowing that you completed it successfully, he asks your help understanding the operation of the quicksort procedure, which he translated from the Python code given in the lab handout:

```
def quicksort(array, left, right):
   if left < right:</pre>
      pivotIndex = partition(array,left,right)
      quicksort(array,left,pivotIndex-1)
      quicksort(array,pivotIndex+1,right)
```

You recall from your lab that each of the three arguments and the local variable are 32bit binary integers. You explain to Harry that quicksort returns no value, but is called for its effect on the contents of a region of memory dictated by its argument values. Harry asks some questions about the possible effect of the call quicksort(0×1000, 0×10, 0×100):

Harry's translation of quicksort to Beta assembly language appears above on the right.

2. What register did Harry choose to hold the value of the variable **pivotIndex**?

Register holding pivotIndex value: R

After loading and assembling this code in BSim, Harry has questions about its translation to binary.

3. Give the hex value of the 32-bit machine instruction with the tag aa in the program to the right.

Hex translation of instruction at aa: 0x

```
quicksort:
      PUSH(LP)
      PUSH(BP)
      MOVE(SP, BP)
      PUSH(R1)
      PUSH(R2)
      PUSH(R3)
      PUSH(R4)
      LD(BP, -12, R1)
      LD(BP, -16, R2)
      LD(BP, -20, R3)
aa:
      CMPLT(R2, R3, R0)
      BF(R0, qx)
      PUSH(R3)
      PUSH(R2)
      PUSH(R1)
      BR(partition, LP)
      DEALLOCATE(3)
      MOVE(R0, R4)
XX:
      SUBC(R4, 1, R0)
      PUSH(R0)
      PUSH(R2)
      PUSH(R1)
      BR(quicksort, LP)
      DEALLOCATE(3)
      PUSH(R3)
      ADDC(R4, 1, R0)
      PUSH(R0)
      PUSH(R1)
      BR(quicksort, LP)
bb:
      DEALLOCATE(3)
      P0P(R4)
qx:
      P0P(R3)
      P0P(R2)
      P0P(R1)
      MOVE(BP, SP)
cc:
      POP(BP)
      POP(LP)
      JMP(LP)
```

Harry tests his code, which seems to work fine. He questions whether it could be shortened by simply eliminating certain instructions. Would Harry's quicksort continue to work properly if the instruction at bb were eliminated? If the instruction at cc were eliminated? Indicate which, if any, of these instructions could be deleted. OK to delete instruction at bb?
Yes
○ No
OK to delete instruction at cc?
Yes
○ No
quicksort(Y, O, X) via a BR(quicksort, LP) at address 0×948. Harry halts its execution just as the instruction following the xx tag is about to be executed. The contents of a region of memory containing the topmost locations on the stack is shown to the right.
What are the arguments to the current quicksort call? Use the stack trace shown above to answer this question. Arguments: array = 0x
left = 0x

6. What is the value **X** in the original call **quicksort(Y, 0, X)**?

The following C program implements a function (ffo) of two arguments, returning an integer result. The assembly code for the procedure is shown on the right, along with a partial stack trace showing the execution of ffo(0xDECAF,0). The execution has been halted just as the Beta is about to execute the instruction labeled rtn, i.e., the value of the Beta's program counter is the address of the first instruction in POP(R1). In the C code below, note that "v>>1" is a logical right shift of the value v by 1 bit.

```
// bit position of left-most 1
int ffo(unsigned v, int b) {
    if (v == 0) ???;
    else return ffo(v>>1,b+1);
}
```

1. Examining the assembly language for ffo, what is the appropriate C code for ??? in the C representation for ffo?

C code for ???:

return b		0x000F	ffo:	PUSH(LP)
<u> </u>		0x001B	110.	PUSH(BP)
return 0		0x0208		MOVE(SP, BP)
		0x012C		PUSH(R1)

It was mentioned in lecture that recursion became a popular programming construct following the adoption of the stack as a storage allocation mechanism, ca. 1960. But the Greek mathematician Euclid, always ahead of his time, used recursion in 300 BC to compute the greatest common divisor of two integers. His elegant algorithm, translated to C from the ancient greek, is shown below:

```
int gcd(int a, int b) {
   if (a == b) return a;
  if (a > b) return gcd(a-b, b);
  else return gcd(a, b-a);
}
```

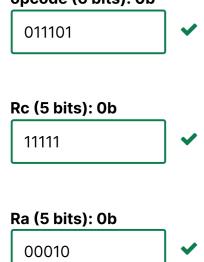

The procedure **gcd(a, b)** takes two positive integers **a** and **b** as arguments, and returns the greatest positive integer that is a factor of both **a** and **b**.

Note that the base case for this recursion is when the two arguments are equal (== in C tests for equality), and that there are two recursive calls in the body of the procedure definition.

Although Euclid's algorithm has been known for millennia, a recent archeological dig has uncovered a new document which appears to be a translation of the above C code to Beta assembly language, written in Euclid's own hand. The Beta code is known to work properly, and is shown below.

```
PUSH(LP)
gcd:
        PUSH(BP)
        MOVE(SP, BP)
        PUSH(R1)
        PUSH(R2)
        LD(BP, -12, R0)
        LD(BP, -16, R1)
        CMPEQ(R0, R1, R2)
        BT(R2, L1)
        CMPLE(R0, R1, R2)
        BT(R2, L2)
XXX:
        PUSH(R1)
        SUB(R0, R1, R2)
        PUSH(R2)
        BR(gcd, LP)
        DEALLOCATE(2)
        BR(L1)
L2:
        SUB(R1, R0, R2)
        PUSH(R2)
        PUSH(R0)
        BR(gcd, LP)
        DEALLOCATE(2)
L1:
        P0P(R2)
        P0P(R1)
        MOVE(BP, SP)
ууу:
        POP(BP)
        POP(LP)
        JMP(LP)
```

1. Give the 32-bit binary translation of the BT(R2,L2) instruction at the label xxx opcode (6 bits): 0b

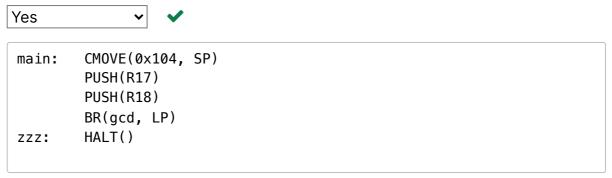

literal (16 bits): 0b

00000000000100

2. One historian studying the code, a Greek major from Harvard, questions whether the **MOVE(BP, SP)** instruction at **yyy** is really necessary. If this instruction were deleted from the assembly language source and re-translated to binary, would the shorter Beta program still work properly?

Still works?

At a press conference, the archeologists who discovered the Beta code give a demonstration of it in operation. They use the test program shown above to initialize SP to hex **0×104**, and call gcd with two positive integer arguments from **R17** and **R18**. Unfortunately, the values in these registers have not been specified.

Address in Hex Data in Hex

100: 104 104: 18 108: 10C:D8110: D4114: EFBA118: 11C: \boldsymbol{F} 120: 9 124: 78 128: 114 12C:18 **130**: \boldsymbol{F} 134: 6 138:

13C:78 **140**: 12C144: \boldsymbol{F} 148: 6 14C:6 150: 3 154: 58 158: 144

 $SP \rightarrow 15C: 6$

They start their program on a computer designed to approximate the computers of Euclid's day (think of Moore's law extrapolated back to 300 BC!), and let it run for a while. Before the call to gcd returns, they stop the computation just as the instruction at **yyy** is about to be executed, and examine the state of the processor.

They find that **SP** (the stack pointer) contains **0×15C**, and the contents of the region of memory containing the stack as shown (in **HEX**) to the right.

You note that the instruction at **yyy**, about to be executed, is preparing for a return to a call from gcd(a,b).

3. What are the values of **a** and **b** passed in the call to gcd which is about to return? Answer in HEX.

4. What are the values of **a** and **b** passed in the *original* call to gcd, from registers **R17** and **R18**? Answer in HEX.

5. What is the address corresponding to the tag **zzz**: of the **HALT()** following the original call to **gcd**?

Address of zzz: (HEX): 0x

6. What is the address corresponding to the tag L1: in the assembly b for gcd?

Address of L1: (HEX): 0x

7. What value will be returned (in R0) as the result of the original call to **gcd**? **Value returned to original caller: (HEX): 0x**

8. What was the value of R2 at the time of the original call to gcd?

Original value in R2: (HEX): 0x

The **wfps** procedure determines whether a string of left and right parentheses is well balanced, much as your Turing machine of Lab 4 did. Below is the code for the wfps ("well-formed paren string") procedure in C, as well as its translation to Beta assembly code.

```
int STR[100];
                         // string of parens
int wfps(int i,
                         // current index in STR
 int n)
                         // LPARENs to balance
{ int c = STR[i];
                         // next character
 int new_n;
                         // next value of n
 if (c == 0)
                        // if end of string,
   return (n == 0);
                       // return 1 iff n == 0
 else if (c == 1)
                        // on LEFT PAREN,
   new_n = n+1;
                        //
                              increment n
   else {
                         // else must be RPAREN
     xxxxx; }
                         // MYSTERY CODE!
 return wfps(i+1, new_n); // and recurse.
}
```

```
6/18/24, 7:47 AM
      STR:

            PUSH(R0)
            BR(wfps, LP)
            DEALLOCATE(2)
            BR(rtn)
```

wfps expects to find a string of parentheses in the integer array stored at STR. The string is encoded as a series of 32-bit integers having values of

- 1 to indicate a left paren,
- 2 to indicate a right paren, or
- 0 to indicate the end of the string.

These integers are stored in consecutive 32-bit locations starting at the address **STR**.

wfps is called with two arguments:

1. The first, i, is the index of the start of the part of STR that this call of wfps should examine. Note that indexes start at 0 in C. For example, if i is 0, then wfps should examine the entire string in STR (starting at the first character, or STR[0]). If i is

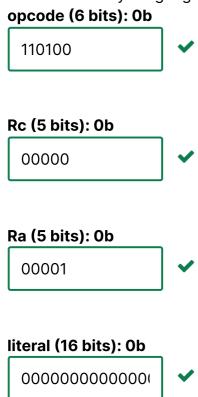

- 4, then wfps should ignore the first four characters and start examining STR starting at the fifth character (the character at STR[4]).
- 2. The second argument, **n**, is zero in the original call; however, it may be nonzero in recursive calls.

wfps returns 1 if the part of STR being examined represents a string of balanced parentheses if **n** additional left parentheses are prepended to its left, and returns 0 otherwise.

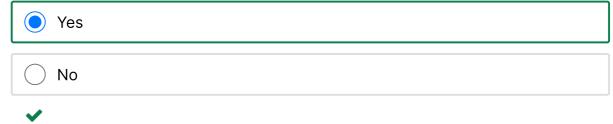

Note that the compiler may use some simple optimizations to simplify the assemblylanguage version of the code, while preserving equivalent behavior.

The C code is incomplete; the missing expression is shown as **xxxx**.

1. Fill in the binary value of the instruction stored at the location tagged more in the above assembly-language program.

2. Is the variable c from the C program stored as a local variable in the stack frame?

If so, give its (signed) offset from BP; else select "NA".

You've taken a summer internship with BetaSoft, the worlds largest supplier of Beta software. They ask you to help with their library procedure sqr(i), which computes the square of a non-negative integer argument j. Because so many Betas don't have a multiply instruction, they have chosen to compute sqr(j) by adding up the first j odd integers, using the C code below and its translation to Beta assembly language to the left.

```
int sqr(j) {
   int s = 0;
   int k = j;
   while (k != 0) {
      s = s + nthodd(k);
      k = k - 1;
   }
   return s;
}
int nthodd(n) {
   if (n == 0) return 0;
   return ???;
}
```

You notice that the **sqr** procedure takes an integer argument j, and declares two local integer variables s and k (initialized to zero and j, respectively).

The body of **sqr** is a loop that is executed repeatedly, decrementing the value of k at each iteration, until k reaches zero. Each time through the loop, the local variable s incremented by the value of the kth odd integer, a value that is computed by an auxiliary procedure nthodd.

1. What is the missing expression shown as ??? in the C code defining **nthodd**

What is the missing expression denoted ??? in above C code:

PUSH (LP) sqr: PUSH (BP) MOVE (SP, BP) ALLOCATE(2) PUSH (R1) ST(R31, 0, BP) LD (BP, -12, R0) ST(R0, 4, BP) loop: LD(BP, 4, R0) BEQ(R0, done) PUSH(R0) SUBC(R0, 1, R0) ST(R0, 4, BP) BR(nthodd, LP) DEALLOCATE(1) LD(BP, 0, R1) ADD(R0, R1, R1) ST(R1, 0, BP) BR(loop) done: LD(BP, 0, R0) P0P(R1) DEALLOCATE(2) MOVE(BP, SP) POP(BP) POP(LP) JMP(LP) nthodd: PUSH (LP) PUSH (BP) MOVE (SP, BP) LD (BP, -12, R0) BEQ(R0, zero) ADD(R0, R0, R0) SUBC(R0, 1, R0) MOVE(BP, SP) zero: POP(BP) POP(LP) JMP(LP)

2. What variable in the C code, if any, is loaded into R0 by the LD instruction tagged **loop**? Answer "none" if no such value is loaded by this instruction.

Value loaded by instruction at loop:, or "none":

Using a small test program to run the above assembly code, you begin computing $\mathbf{sqr}(\mathbf{X})$ for some positive integer \mathbf{X} , and stop the machine during its execution. You notice, from the value in the PC, that the instruction tagged \mathbf{zero} is about to

be executed. Examining memory, you find the following values in a portion of the area reserved for the Beta's stack.

F0: F4

5 F4:

ECF8:

D4FC:

15 100:

1 104:

DECAF108:

2 10C

4C110

100 114

*BP*118: 0 \rightarrow

NB: All values are in HEX! Give your answers in hex, or write "CAN'T TELL" if you can't tell.

You notice that BP contains the value **0×118**.

3. What argument (in hex) was passed to the current call to nthodd? Answer "CAN'T TELL" if you can't tell.

HEX Arg to nthodd, or "CAN'T TELL": 0x

4. What is the value X that was passed to the original call to sqr(X)? Answer "CAN'T TELL" if you can't tell.

HEX Arg X to sqr, or "CAN'T TELL": 0x

5. What is the hex value in SP? Answer "CAN'T TELL" if you can't tell.

HEX Value in SP, or "CAN'T TELL": 0x

6. What is the current value of the variable k in the C code for sqr? Answer "CAN'T TELL" if you can't tell.

HEX Value of k in sqr, or "CAN'T TELL": 0x

7. The test program invoked sqr(X) using the instruction BR(sqr,LP). What is the address of that instruction? Answer "CAN'T TELL" if you can't tell.

HEX Address of BR instruction that called sqr, or "CAN'T TELL": 0x

What value was in R1 at the time of the call to sqr(X) ? Answer "CAN'T TELL" if you can't tell.
HEX Value in R1 at call to sqr, or "CAN'T TELL": 0x
Your boss at BetaSoft, Les Ismoore, suspects that some of the instructions in t

the Beta code could be eliminated, saving both space and execution time. He hands you an annotated listing of the code (shown below), identical to the original assembly code but with some added tags.

```
sqr:
        PUSH (LP)
        PUSH (BP)
        MOVE (SP, BP)
        ALLOCATE(2)
        PUSH (R1)
        ST(R31, 0, BP)
        LD (BP, -12, R0)
        ST(R0, 4, BP)
        LD(BP, 4, R0)
loop:
        BEQ(R0, done)
        PUSH(R0)
        SUBC(R0, 1, R0)
        ST(R0, 4, BP)
        BR(nthodd, LP)
        DEALLOCATE(1)
        LD(BP, 0, R1)
        ADD(R0, R1, R1)
        ST(R1, 0, BP)
        BR(loop)
done:
        LD(BP, 0, R0)
        P0P(R1)
q1:
        DEALLOCATE(2)
        MOVE(BP, SP)
        POP(BP)
        POP(LP)
        JMP(LP)
nthodd: PUSH (LP)
q5:
        PUSH (BP)
q2:
        MOVE (SP, BP)
        LD (BP, -12, R0)
        BEQ(R0, zero)
        ADD(R0, R0, R0)
        SUBC(R0, 1, R0)
zero:
        MOVE(BP, SP)
        POP(BP)
        POP(LP)
        JMP(LP)
```

Les proposes several optimizations, each involving just the deletion of one or more instructions from the annotated code. He asks, in each case, whether the resulting code would still work properly. For each of the following proposed deletions, select "OK" if the code would still work after the proposed deletion, or "NO" if not. For each question, **assume that the proposed deletion is the ONLY change** (i.e., you needn't consider combinations of proposed changes).

9. Delete the instruction tagged q1.

Proposed deletion OK or NO?

	Ок	
	O NO	
10.	Delete the	e instruction tagged q2 .
		deletion OK or NO?
	Ок	
	O NO	
11		
		e instruction tagged loop . I deletion OK or NO?
	ОК	
	O NO	
		e instruction tagged zero . I deletion OK or NO?
	Ок	
	O NO	
		e back-and-forth with Les, he proposes to replace nthodd with a version that avoids much of the standard procedure linkage e:
	nthodd:	LD (SP, NNN, R0) BEQ(R0, zero) ADD(R0, R0, R0) SUBC(R0, 1, R0)

He's quite sure this code will work, but doesn't know the appropriate value for NNN.

13. What is the proper value for the constant **NNN** in the shortened version of nthodd?

JMP(LP)

zero:

Appropriate value for NNN (in decimal):

Submit

You are given the following listing of a C program and its translation to Beta assembly code:

```
// Mystery function:
int f(int x, int y) {
  int a = (x+y) >> 1;
  if (a == 0) return y;
 else return ???;
}
```

(Recall that a >> b means a shifted b bits to the right, propagating – ie, preserving -- sign)

1. Fill in the binary value of the BR instruction stored at the location tagged yy in the above program.

opcode (6 bits): 0b

011100

Rc (5 bits): 0b

11100

Ra (5 bits): 0b

11111

literal (16 bits): 0b

1111111111101100

```
f:
     PUSH(LP)
     PUSH(BP)
     MOVE(SP, BP)
     PUSH(R1)
     PUSH(R2)
     LD(BP, -12, R1)
     LD(BP, -16, R0)
     ADD(R0, R1, R2)
     SRAC(R2, 1, R2)
     BEQ(R2, bye)
XX:
     SUB(R1, R2, R1)
     PUSH(R1)
     PUSH(R0)
     BR(f, LP)
уу:
     DEALLOCATE(2)
     ADD(R2, R0, R0)
bye: POP(R2)
     P0P(R1)
     MOVE(BP, SP)
ZZ:
     POP(BP)
     POP(LP)
     JMP(LP)
```

2. Suppose the MOVE instruction at the location tagged zz were eliminated from the above program. Would it continue to run correctly?

Still works fine?

YES

NO

3. What is the missing expression designated by ??? in the C program above.

The procedure **f** is called from an external procedure and its execution is interrupted during a recursive call to f, just prior to the execution of the instruction tagged bye. The contents of a region of memory are shown below.

NB: All addresses and data values are shown in hex. The BP register contains 0×250, SP contains 0×258, and R0 contains 0×5.

CC204:

4 208:

20C: 7

6 210:

7 214:

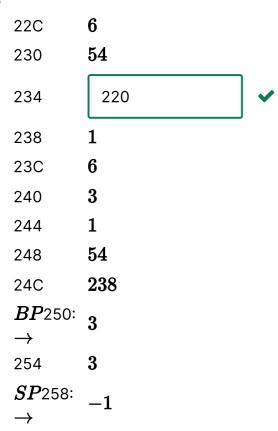

E8218:

D421C:

BAD220:

BABE224

228 1

4. What are the arguments to the *most recent* active call to **f**?

Most recent arguments (HEX): x = 0x

- 5. Fill in the missing value in the stack trace.
- 6. What are the arguments to the *original* call to **f**?

Original arguments (HEX): x = 0x

7

7. What value is in the **LP** register?

Contents of LP (HEX): 0x

8. What value was in R1 at the time of the original call?

Contents of R1 (HEX): 0x

BAD

9. What value will be returned in R0 as the value of the original call? [HINT: You can figure this out without getting the C code right!].

Value returned to original caller (HEX): 0x

10. What is the hex address of the instruction tagged yy?

Address of yy (HEX): 0x

Submit

You are given the following listing of a C program and its translation to Beta assembly code:

```
int f(int x, int y) {
  int a = (x+y) >> 2;
  if (a == 0) return x;
  else return y + f(a, x+a);
}
```

(Recall that a >> b means a shifted b bits to the right, propagating – ie, preserving -- sign)

1. Fill in the binary value of the BEQ instruction stored at the location tagged **laby** in the above program.

```
opcode (6 bits): 0b
```

```
Rc (5 bits): 0b
```

```
f:
       PUSH(LP)
       PUSH(BP)
       MOVE(SP, BP)
       PUSH(R1)
       LD(BP, -12, R0)
       LD(BP, -16, R1)
       ADD(R0, R1, R1)
       SRAC(R1, 2, R1)
       BEQ(R1, labx)
laby:
       ADD(R0, R1, R0)
       PUSH(R0)
       PUSH(R1)
       BR(f, LP)
       DEALLOCATE(2)
labz:
       LD(BP, -16, R1)
       ADD(R1, R0, R0)
labx:
       P0P(R1)
       MOVE(BP, SP)
       POP(BP)
       POP(LP)
       JMP(LP)
```

	Ra (5 bi	ts): 0b
	literal (1	6 bits): 0b
2.	offset fr	ation reserved for the argument x in f 's stack frame? Give its (signed) om BP , or NONE if there is no such location. of x (in decimal), or "NONE":
3.	from BP	ntion reserved for the variable a in f 's stack frame? Give its (signed) offset , or NONE if there is no such location. of variable a, or "NONE":
	interrup	cedure f is called from an external procedure and its execution is ted during a recursive call to f , just prior to the execution of the ion tagged labz . The contents of a region of memory are shown below.
